I have a comment regarding the Estimating GHG Emission Reductions from Planned Degradation (Improved Forest Management) Methodology.

According to the published document, the methodology is only applicable for Tropical rainforests, Insular Asia. It is considered that methodologies should have a comprehensive approach enabling its use by other projects in different places, obviously, under the same applicability conditions. I consider that the methodology could be applied for several locations around the world, where forests were degraded due to logging, either by legal logging or commercial firewood harvesting.

I ask you to consider expanding the geographic range of the methodology, so that it applies to all types of forests or explain which are the specific reasons to limit the projects to Tropical Rainforests, Insular Asia.
