Section I: Summary and applicability of the baseline and monitoring methodology

Acknowledgements: The BioCarbon Fund acknowledges the lead author of this methodology: Neil Bird. We are also grateful to external reviewers, Timm Tennigkeit, Matthias Seebauer, Giuliana Zanchi, and internal reviewers from the World Bank, Neeta Hooda and Rama Chandra Reddy that contributed to the development of this methodology.

I.1 Brief description

This methodology proposes to estimate and monitor greenhouse gas emissions of project activities that reduce emissions in agriculture through adoption of sustainable land management practices (SALM) in the agricultural landscape. In this methodology, SALM is defined as any practice that increases the carbon stocks on the land. Examples of SALM are (but are not limited to) manure management, use of cover corps, and returning composted crop residuals to the field and the introduction of trees into the landscape. The methodology is applicable to areas where the soil organic carbon would remain constant or decrease in the absence of the project.

The methodology in its current form is applicable only for use of Roth-C model. The estimates of uncertainty and Activity Baseline and Monitoring Survey (ABMS) in the current methodology are adapted for the Roth-C model only. Application of the methodology for use of other models will require at a minimum, revisions to estimates of uncertainty and ABMS specific to the model applied. If however, the parameters used by another model correspond to some or all parameters included in this methodology, then the methodology is applicable, provided applicability conditions of the methodology are met.

This methodology is based on the project “Western Kenya Smallholder Agriculture Carbon Finance project” in Kenya. The baseline study, monitoring and project document are being prepared by the Foundation Vi Planterar trad (“We plant trees”) with assistance from Unique Forestry Consultants Ltd., the Swedish International Agency (Sida) and the International Bank for Reconstruction and Development as Trustee of the Biocarbon Fund.

I.2 Applicability conditions

This methodology is applicable to projects that introduce sustainable agriculture land management practices (SALM) into an agricultural landscape subject to the following conditions:

a) Land is either cropland or grassland at the start of the project;
b) The project does not occur on wetlands;
c) The land is degraded and will continue to be degraded or continue to degrade;
d) The area of land under cultivation in the region is constant or increasing in absence of the project;
e) Forest land, as defined by the national CDM forest definition, in the region is constant or decreasing over time;
f) There must be studies (for example: scientific journals, university theses, local research studies or work carried out by the project proponent) that demonstrate that the use of the Roth-C model \(^1\) is appropriate for: (a) the IPCC climatic regions of 2006 IPCC AFOLU

---

\(^1\) For ROTH-C see [http://www.rothamsted.bbsrc.ac.uk/aen/carbon/rothc.htm](http://www.rothamsted.bbsrc.ac.uk/aen/carbon/rothc.htm).
Guidelines or (b) the agroecological zone (AEZ) in which the project is situated, using one of options presented below:

**Option 1:** The studies used in support of the project should meet the guidance on model applicability as outlined in IPCC AFOLU 2006 guidelines in order to show that the model is applicable for the relevant IPCC climatic region. The guidance notes that an appropriate model should be capable of representing the relevant management practices and that the model inputs (i.e., driving variables) are validated from country or region-specific locations that are representatives of the variability of climate, soil and management systems in the country.

**Option 2:** Where available, the use of national, regional or global level agroecological zone (AEZ) classification is appropriate to show that the model has been validated for similar AEZs. It is recognized that national level AEZ classifications are not readily available; therefore this methodology allows the use of the global and regional AEZ classification.

Where a project area consists of multiple sites, it is recognized that studies demonstrating model validity using either Option 1 or Option 2 may not be available for each of the sites in the project area. In such cases the study used should be capable of demonstrating that the following two conditions are met:

(i) The model is validated for at least 50% of the total project area where the project area covers up to 50,000 ha; or at least 75% of the total project area where project area covers greater than 50,000 ha; and

(ii) The area for which the model is validated generates at least two-thirds of the total project emission reductions.

**Explanation / justification**

Applicability conditions (a) - (d) allow for the simplification of the baseline. With these conditions we conservatively assume that the lands of a given land use type are degrading in absence of the project. Specifically it is likely that:

a) if the land is cropland, then it will remain cropland in absence of the project; otherwise
b) the land is grasslands that will remain grassland or be converted to croplands in absence of the project.

---

2 The IPCC climatic regions are shown in Figure 3A.5.1 page 3.38.
3 The agro-ecological zone (AEZ) methodology is standardized framework for the characterization of climate, soil and terrain conditions relevant to agricultural production. Crop modelling and environmental matching procedures are used to identify crop-specific limitations of prevailing climate, soil and terrain resources, under assumed levels of inputs and management conditions.
4 The details of global agroecological zones classification outlined by Food and Agricultural Organization of United Nations (FAO), Rome, Italy and International Institute for Applied Systems Analysis, Laxenburg, Austria are available at: [http://www.iiasa.ac.at/Research/LUC/GAEZ/index.htm](http://www.iiasa.ac.at/Research/LUC/GAEZ/index.htm)
5 The project area of 50,000 ha is reasonable taking into account the wide range of soil carbon sequestration rates, which depend on climate, soil and land use characteristics. The project area is also influenced by the rates of SALM adoption that are in turn influenced by factors such as farmer awareness to SALM, institutional support and extension systems. Assuming a conservative soil sequestration rate of 0.5 tC/ha/yr applied in CDM A/R methodologies, a project of 50,000 ha is likely to generate 25,000 tC/ha/yr, and is considered reasonable taking into account the implementation, monitoring and verification costs.
Degradation shall be demonstrated using the latest version of the CDM EB approved tool *Tool for the identification of degraded or degrading lands for consideration in implementing CDM A/R project activities.*

Applicability condition (e) ensures that, in absence of the project, the land would likely not have been:

- a) abandoned and allowed to naturally regenerate to forest, or
- b) afforested or reforested.

With these applicability conditions we can conservatively assume that the soil organic carbon would remain constant or decrease with time in absence of the project.

Finally, the methodology relies on modelled soil organic carbon. To assure that the model results are reasonable, there must be studies (for example; scientific journals, university theses, local research studies or work carried out by the project proponent) that demonstrate the use of the selected model is valid for the project region. This is fulfilled with applicability condition (f) in accordance with the VCS guidance included in Section 2.3 of the VCS Standard Version 3.1 on quantification of GHG emissions and/or removals related to the methodology.

### I.4 Summary description of major baseline and project methodological steps

#### I.4.1 Baseline methodology

The baseline emissions and removals are estimated using the following steps:

1. Identify and delineate the project boundary;
2. Identify the baseline scenario and demonstrate additionality;
3. Estimate the annual emissions from the use of synthetic fertilizers;
4. Estimate the annual emissions from the use of N-fixing species;
5. Estimate the annual emissions from the burning of agricultural residues;
6. Estimate the annual removals from existing woody perennials;
7. Estimate the annual emissions from the use of fossil fuels for agricultural management; and
8. Estimate the equilibrium soil organic carbon in the baseline assuming no changes in agricultural management or agricultural inputs.

I.4.2 Project methodology

The project emissions and removals are estimated using the following steps:
1. Estimate the annual emissions from the use of synthetic fertilizers;
2. Estimate the annual emissions from the use of N-fixing species;
3. Estimate the annual emissions from the burning of agricultural residues;
4. Estimate the annual emissions and removals from woody perennials;
5. Estimate the annual emissions from the use of fossil fuels for agricultural management;

Using the model estimate the parameters in 6, 7 and 8 below:
6. Estimate the equilibrium soil organic carbon in the project based on estimated or measured changes in agricultural management or agricultural inputs;
7. Convert the equilibrium soil organic carbon in the project to transient soil organic carbon assuming a linear transition period;
8. Estimate the annual emissions and removals from soil organic carbon; and
9. Estimate leakage from the increase in the use of non-renewable biomass that occurs from the displacement of biomass used for energy to agricultural inputs.

I.4.3 Monitoring methodology

The following steps are required as part of the monitoring methodology:
1. Record the amount of fossil fuels used in the project;
2. Record the amount of synthetic fertilizers used in the project;
3. Estimate the amount of production of biomass by N-fixing species in the project;
4. Estimate the amount of agricultural residues burnt in the project;
5. Record the production from areas of various types of agricultural land management;
6. Measure the changes in biomass in woody perennials;
7. Estimate the reduction in the amount of biomass used for energy that is a result of the project.

The summary description of major baseline and project methodological steps noted above has been elaborated in the sections II, III and IV of the methodology.
Section II: Baseline methodology description

II.1 Project boundary

The “project boundary” geographically delineates all lands that are under the control of the project proponent for the proposed sustainable agricultural land management (SALM) activities. The SALM project activities may contain more than one discrete area of land.

II.2 Procedure for selection of most plausible baseline scenario

The baseline scenario is identified as existing or historical land management practices. The project proponent shall use the most recent version of the Combined tool to identify the baseline scenario and demonstrate the additionality in A/R CDM project activities, mutatis mutandis.

II.3 Additionality

The project proponent shall use the most recent version of the Combined tool to identify the baseline scenario and demonstrate the additionality in A/R CDM project activities, mutatis mutandis.

II.4 Estimation of baseline GHG emissions and removals

II.4.1 Baseline emissions due to fertilizer use

The baseline emissions from synthetic fertilizer use, $BEF_b$, are calculated using the latest version of the CDM A/R Tool Estimation of direct nitrous oxide emission from nitrogen fertilization.

Emissions from manure application are not expected to change with the project, as the project activity does not result in a change in animal population. For this reason the baseline emissions from manure application can be ignored.

II.4.2 Baseline emissions due to the use of N-fixing species

The baseline emissions from the use of N-fixing species, $BEN_b$, are not calculated, but the project proponent shall record the area under N-fixing species prior to project implementation.

II.4.3 Baseline emissions due to burning of biomass

The baseline emissions due to burning of biomass, $BEBB_b$, are calculated using the tool Estimation of non-CO2 emissions from the burning of crop residues (Section VI.3).

II.4.4 Baseline removals from existing woody perennials

The baseline removals from woody perennials, $BRWP_b$, are calculated using the latest version of the CDM A/R Tool Estimation of carbon stocks and change in carbon stocks of trees and shrubs in A/R CDM project activities.

II.4.5 Baseline emissions from use of fossil fuels in agricultural management

The baseline emissions due to combustion of fossil fuels in agricultural management in baseline, $BEFF_b$, is calculated using the tool Estimation of emissions from combustion the use of fossil fuels in agricultural management (Section VI.2).

---

6 In accordance with the VCS rules.
II.4.6 Equilibrium soil organic carbon density in management systems

Using an analytic model that has been accepted in scientific publications (for example: Roth-C soil organic carbon model\(^3\)) estimate the soil organic carbon (SOC) density to a depth of 30 cm, at equilibrium in identified management practices on cropland and grassland. Soil carbon modelling should count only biomass inputs to soil from within the project boundary.

The SOC density should be estimated using area-weighted average values of model input parameters for each management practice identified in Step 4 under uncertainty analysis.

The baseline soil organic carbon at equilibrium can be estimated using:

\[
BS_{equl,t} = \sum_{m_C} BA_{C,m_C,t} \cdot SOC_{C,m_C} + \sum_{m_G} BA_{G,m_G,t} \cdot SOC_{G,m_G}
\]

Where:

- \(BS_{equl,t}\) Baseline SOC in equilibrium year \(t\), tC
- \(BA_{C,m_C,t}\) Baseline areas in cropland with management practice, \(m_C\), year \(t\), ha
- \(SOC_{C,m_C}\) Soil organic carbon density at equilibrium for cropland with management practice, \(m_C\), tC/ha
- \(m_C\) An index for cropland management types, unit less
- \(BA_{G,m_G,t}\) Baseline areas in grassland with management practice, \(m_G\), year \(t\), ha
- \(SOC_{G,m_G}\) Soil organic carbon density to a depth of 30 cm, at equilibrium for grassland with management practice, \(m_G\), tC/ha
- \(m_G\) An index for grassland management types, unit less

II.4.7 Baseline removals due to changes in soil organic carbon

Since the applicability conditions limit the project to lands that are under agricultural pressure and are degrading, it can be conservatively assumed that the baseline removals due to changes in SOC are zero. Therefore

\[
BRS_t = 0
\]

Where:

- \(BRS_t\) Baseline removals due to changes in soil organic carbon in year \(t\), t CO\(_2\)e.

II.4.8 Total baseline emissions and removals

The total baseline emissions and removals are given by:

\[
BE_t = BEF_t + BEFF_t + BEBB_t - BRWP_t
\]

Where:

- \(BE_t\) Baseline emissions in year \(t\), t CO\(_2\)e
- \(BEF_t\) Baseline emissions due to nitrogen fertilizer use in year \(t\), t CO\(_2\)e.
Baseline emissions due to use of fossil fuels in agricultural management in year $t$, $t\ CO_2e$.

Baseline emissions due to biomass burning in year $t$, $t\ CO_2e$.

Baseline removals due to changes in woody perennials in year $t$, $t\ CO_2e$.

**Section III: Project methodology description**

**III.1 Estimation of project GHG emissions and removals**

Where the sum of increase in greenhouse gas emissions from each of the identified emission sources in the methodology and leakage due to displacement of renewable biomass is insignificant these can be ignored.

**III.1.1 Project emissions due to fertilizer use**

The project emissions from synthetic fertilizer use, $PEF_t$, are calculated using the latest version of the CDM A/R Tool *Estimation of direct nitrous oxide emission from nitrogen fertilization (version 01)*.

Emissions from manure application are not expected to change with the project, as the project activity does not result in a change in the animal population. For this reason the project emissions from manure application can be ignored.

**III.1.2 Project emissions due to the use of N-fixing species**

Only the emissions due to increased area under N-fixing species shall be accounted.

If the area cropped with N-fixing species in the project is more than 50% larger than the area under N-fixing species in the baseline then the project emissions from the use of N-fixing species, $PEN_t$, are calculated using the tool *Estimation of direct nitrous oxide emission from N-fixing species and crop residues* (Section VI.1).

In all other cases estimation of emissions from N-fixing species is not required.

This differentiation is based on the assumption that:

- a) the project does not occur on wetlands;
- b) the project occurs on degraded lands so that the lands are likely nitrogen deficient.

These assumptions mean that the nitrogen emissions tend to be smaller than estimated by the Tier 1 IPCC estimation methodology.

**III.1.3 Project emissions due to burning of biomass**

The project emissions due to burning of biomass, $PEBB_t$, are calculated using the tool *Estimation of non-CO2 emissions from the burning of crop residues* (Section VI.3).

---

7 Significance is defined so that the sum of increase in greenhouse gas emissions from the displacement of renewable biomass and each of emission sources identified in the methodology is less than 5% of the emission reductions by the project. The significance of the emission will be tested using the latest version of the CDM EB approved Tool for testing significance of GHG emissions in A/R CDM project activities ([http://cdm.unfccc.int/methodologies/ARmethodologies/tools/ar-am-tool-04-v1.pdf](http://cdm.unfccc.int/methodologies/ARmethodologies/tools/ar-am-tool-04-v1.pdf))
III.1.4  Project removals from woody perennials
The project removals from woody perennials, PRWP, are calculated using portions of CDM A/R Simplified baseline and monitoring methodologies for small-scale afforestation and reforestation project activities under the clean development mechanism implemented on grasslands or croplands AR-AMS0001e.

III.1.5  Project emissions due to use of fossil fuels for agricultural management
The project emissions due to the use of fossil fuels for agricultural management, PEFF, are calculated using the tool Estimation of emissions from the use of fossil fuels in agricultural management (Section VI.2)

III.1.6  Project equilibrium soil organic carbon density in management systems
Undertake an Activity Baseline and Monitoring Survey (ABMS) to identify the dominant agricultural management practices for croplands and grasslands. The ABMS should estimate or record details of each management practice. For example when using the Roth-C model, one should record:

1. its area;
2. the average annual biomass production from within the project boundary;
3. the average biomass left on site or input;
4. the average number and type of grazing animals;
5. the amount of manure input; and
6. the amount of nitrogen fertilizers input.

Using an analytic model that has been accepted in scientific publications and validated for the project region (for example: Roth-C soil organic carbon model) estimate the soil organic carbon (SOC) density, to a depth of 30 cm, at equilibrium in each of the identified management practices in each of the land use categories (cropland and grassland). The soil carbon modelling should count only biomass inputs to soil from within the project boundary.

The details of each management practice that are recorded will depend on the choice of soil model selected and the type of activity being promoted. For example, if the activity is improving the use of crop residues then for use with the Roth-C model, the ABMS should record:

- Area of each crop (ha)
- Productivity of each crop (kg/ha)
- The amount of crop residues (kg/ha)\(^8\)
- Existing crop residue management practices and their frequency
- Future crop residue management practices that will be implemented with the project

If the project activity includes improving the management of manure, then for use with the Roth-C model, the ABMS should also record:

- Area of grazing (ha)
- The number of livestock per animal type
- The amount of manure produced (kg/ha or kg/an)\(^9\)
- Existing manure management practices and their frequency

---

\(^8\) Amount of crop residues need not be measured directly. It can also be estimated from the crop production using equations listed in Table 11.2 in Volume 4 of the 2006 IPCC Guidelines

\(^9\) Amount of manure need not be measured directly. It can also be estimated from the number and type of animal using values from Table 10A-4 in Chapter 10 of the 2006 IPCC Guidelines.
Future manure management practices that will be implemented with the project

If the project activity includes improved tillage practices, then for use with the Roth-C model, the ABMS should record:

- Area under tillage (ha)
- Type and depth of tillage
- Existing tilling practices and their frequency
- Future tilling practices that will be implemented with the project

If the project activity includes agroforestry, then, for use with the Roth-C model, the ABMS should record:

- Area of agroforestry (ha)
- Number and species of trees used
- Diameter at breast height (DBH) of trees
- Future numbers of trees that will be implemented with the project

The applicability of the selected model and parameters recorded for the various activities, and soil and climate types are dependent on the actual project. Since these are project specific and not methodology specific, they should be discussed in detail in the project description.

The SOC density should be estimated using area-weighted average values of model input parameters for each management practice identified.

The project soil organic carbon at equilibrium can be estimated using:

$$ PS_{equil,t} = \sum_{m_C} PA_{C,m_C,t} \cdot SOC_{C,m_C,t} + \sum_{m_G} PA_{G,m_G,t} \cdot SOC_{G,m_G,t} $$

Where:

- $PS_{equil,t}$: Project SOC in equilibrium year t, tC
- $PA_{C,m_C,t}$: Project areas in cropland with management practice, $m_C$, year t, ha
- $SOC_{C,m_C,t}$: Soil organic carbon density at equilibrium for cropland, to a depth of 30 cm, with management practice, $m_C$, at year t, tC/ha
- $m_C$: An index for cropland management types, unit less
- $PA_{G,m_G,t}$: Project areas in grassland with management practice, $m_G$, year t, ha
- $SOC_{G,m_G,t}$: Soil organic carbon density at equilibrium, to a depth of 30 cm, for grassland with management practice, $m_G$, at year t, tC/ha
- $m_G$: An index for grassland management types, unit less

### III.1.7 Project estimate of soil organic carbon with transitions

The estimate of soil organic carbon with transitions can be estimated using:

$$ PS_t = \frac{1}{D} \sum_{t=0}^{t} PS_{equil,t} \cdot \Delta t $$
Where:

\( PS_t \) Estimate of the project SOC in year \( t \), tC

\( PS_{\text{equil},t} \) Estimate of the project SOC in equilibrium year \( t \), tC

\( D \) The transition period required for SOC to be at equilibrium after a change in land use or management practice, year

\( \Delta t \) Time increment = 1 year

For values of \( t-D+1 \) less than zero (the start of the project) assume that \( PS_{\text{equil},t} = BS_{\text{equil},t-D} \).

These values are required if one is trying to estimate the absolute soil organic carbon in the baseline. Since the ultimate goal of the methodology is the increase or decrease in SOC with the project these values are not required since they appear in both the baseline and project estimation technique.

Value of \( D \) may be chosen from published data from local or regional studies or the modelling exercise. In absence of such data, the IPCC Tier 1 methodology default factor of 20 years may also be used.

### III.1.8 Estimate of project removals due to changes in soil organic carbon

The estimate of project removals due to changes in soil organic carbon is given by:

\[
PRS_t = (PS_t - PS_{t-D}) \cdot \frac{44}{12}
\]

Where:

\( PRS_t \) Estimate of project removals due to changes in soil organic carbon in year \( t \), t CO\(_2\)e.

\( PS_t \) Estimate of the project SOC in year \( t \), tC

\( PS_{t-D} \) Estimate of the project SOC in year \( t-D \), tC

### III.1.9 Actual net GHG emissions and removals by sinks

The actual net GHG emissions and removals by sinks are given by:

\[
PE_t = PEF_t + PEFF_t + PEN_t + PEBB_t - PRWP_t - PRS_t
\]

Where:

\( PE_t \) Estimate of actual net project GHG emissions and removals by sinks in year \( t \), t CO\(_2\)e

\( PEF_t \) Estimate of project emissions due to nitrogen fertilizer use in year \( t \), t CO\(_2\)e.

\( PEFF_t \) Estimate of project emissions due to burning of fossil fuels for agricultural management in year \( t \), t CO\(_2\)e.

\( PEN_t \) Estimate of project emissions due to the increase use of N-fixing species in year \( t \), t CO\(_2\)e.

\( PEBB_t \) Estimate of project emissions due to biomass burning in year \( t \), t CO\(_2\)e.

\( PRWP_t \) Estimate of project removals due to changes in biomass of woody perennials in year \( t \), t CO\(_2\)e.
PRS, Estimate of project removals due to changes in soil organic carbon in year t, t CO2e.

### III.2 Estimation of leakage

The one potential source of leakage is an increase in the use of fuel wood and/or fossil fuels from non-renewable sources for cooking and heating purposes due to the decrease in the use of manure and/or residuals as an energy source.

Leakage due to the increase in the use of fuel wood from non-renewable sources for cooking and heating purposes may be a significant source of leakage if manure or other agricultural residuals used for cooking and heating are transferred to the fields as part of the project. In the project, this could be minimized by the introduction of woody perennials for fuel in the landscape and/or improvement of energy efficiency of biomass for cooking and heating. In situations of this form of leakage, the leakage from a switch to non-renewable biomass use, LNRB, is calculated in accordance with Section IV.2.6 (which is adapted from the small scale methodology AMS-I.E. Switch from Non-Renewable Biomass for Thermal Applications by the User).

However, where this is significant, leakage due to switch to fossil fuels (LFF) shall be estimated in accordance with Equation 11 in Section IV.2.6.

### III.3 Estimation of net anthropogenic GHG emissions and removals

The estimation of net anthropogenic GHG removal by sinks is made using:

\[
\Delta R_t = BE_t - PE_t - LHE_t
\]

Where:

- \( \Delta R_t \) Estimate of net anthropogenic GHG emissions and removals in year t, t CO2e
- \( PE_t \) Estimate of actual net project GHG emissions and removals in year t, t CO2e
Baseline emissions and removals in year \( t \), t CO\(_2\)e

The leakage from a switch to non-renewable biomass or fossil fuel in place of the biomass used for cooking/heating diverted to agricultural system in year \( t \), t CO\(_2\)e

**Section IV: Monitoring methodology description**

**IV.1 Baseline GHG emissions and removals**

**IV.1.1 Sampling design**

The project proponent shall use the CDM EB approved *General Guidelines For Sampling And Surveys For Small-Scale CDM Project Activities* for sampling and survey design. At the start of the project, the project proponent shall undertake an Activity Baseline and Monitoring Survey (ABMS) to identify the dominant agricultural management practices for croplands and grasslands. The ABMS should estimate or record details of each management practice. For example when using the Roth-C model, one should record:

1. its area;
2. the annual biomass production from within the project boundary;
3. the annual biomass left on the fields;
4. the number and type of grazing animals;
5. the amount of manure input;
6. the amount of nitrogen fertilizers input;
7. the amount of N-fixing species;
8. the amount of biomass burnt; and
9. the existence and amount of woody perennials (trees and bushes).

The information recorded will depend on the choice of soil model selected and the type of activity being promoted. For example, if the project activity is improving the use of crop residues then for use with the Roth-C model, the ABMS should record in the baseline:

- Area of each crop (ha)
- Productivity of each crop (kg/ha)
- The amount of crop residues (kg/ha)
- Existing crop residue management practices and their frequency
- Future crop residue management practices that will be implemented with the project

If the project activity includes improving the management of manure, then for use with the Roth-C model, the ABMS should record in the baseline:

- Area of grazing (ha)
- The number of livestock per animal type
- The amount of manure produced (kg/ha or kg/an)\(^{11}\)

\(^{10}\) Amount of crop residues need not be measured directly. It can also be estimated from the crop production using equations listed in Table 11.2 in Volume 4 of the 2006 IPCC Guidelines.

\(^{11}\) Amount of manure need not be measured directly. It can also be estimated from the number and type of animal using values from Table 10A-4 in Chapter 10 of the 2006 IPCC Guidelines.
• Existing manure management practices and their frequency
• Future manure management practices that will be implemented with the project

If the project activity includes improved tillage practices, then for use with the Roth-C model, the ABMS should record in the baseline:
• Area under tillage (ha)
• Type and depth of tillage
• Existing tilling practices and their frequency
• Future tilling practices that will be implemented with the project

If the project activity includes agroforestry, then for use with the Roth-C model, the ABMS should record in the baseline:
• Area of agroforestry (ha)
• Number and species of trees used
• Diameter at breast height (DBH) of trees
• Future numbers of trees that will be implemented with the project

The applicability of the selected model and parameters recorded for the various activities, and soil and climate types are dependent on the actual project. Since these are project specific and not methodology specific, they should be discussed in detail in the project description.

Other model input parameters that may be required by the selected model, such as climatic data, clay content and texture of soils\(^1\) can be acquired from global or national data sets and do not need to be measured by the project proponent. The project proponent may use climatic data collected by the meteorological station/s in proximity to the project area or use published data and determine the relevance of this data to the project in the following ways:

• The data being applied to the project has been obtained from one or more meteorological station/s whose meteorological coverage includes the project area.

• The data being applied to the project has been obtained from one or more meteorological station/s whose meteorological coverage can be shown to be applicable to the project area based on expert opinion.

• Where data from a meteorological station/s is not available, project entities may use published climatic data by demonstrating that such data is applicable to the project area, using expert opinion.

It is recommended that the project proponent stratifies by crop system, tillage system, use of crop residues, application of manure and clay content of soils and relevant climatic variables as a minimum.

</table>
IV.2 *Ex-ante and ex-post net anthropogenic GHG emissions and removals*

IV.2.1 Data to be collected and archived for *ex-ante* project GHG emissions and removals

Record all assumptions and sources of assumptions.

IV.2.2 Data to be collected and archived for *ex-ante* leakage

The only source of leakage possible as a result of the project is the leakage from a switch to non-renewable biomass use or fossil fuels. Procedures to estimate leakage have been included ex-post; the ex-ante estimate of leakage is zero.

IV.2.3 Monitoring of project implementation

The project proponent should record when each farmer within the project area enters into agreement to adopt sustainable agricultural land management practices.

Each farmer should be given a unique ID. Their name, location of their lands, and date of entering into the agreement and leaving the agreement should be recorded.

IV.2.4 Sampling design

The project proponent shall use the CDM EB approved *General Guidelines For Sampling And Surveys For Small-Scale CDM Project Activities* for sampling and survey design. They should undertake an Activity Baseline and Monitoring Survey (ABMS) on a regular basis (annually or bi-annually) to identify the actual agricultural management practices adopted on croplands and
grasslands. The ABMS should estimate or record details of each management practice. For example when using the Roth-C model, one should record:

1. its area;
2. the annual biomass production;
3. the annual biomass left on the fields;
4. the number and type of grazing animals;
5. the amount of manure input;
6. the amount of nitrogen fertilizers input;
7. the amount of N-fixing species;
8. the amount of biomass burnt; and
9. the biomass of woody perennials (trees and bushes).

The following parameters need to be recorded annually.

1. Regional total biomass production;
2. Annual temperature, precipitation and evapotranspiration and
3. Fertilizer price.
4. The amount of fossil fuel used for agricultural management

The information recorded will depend on the choice of soil model selected and the type of activity being promoted. For example, if the activity is improving the use of crop residues then for use with the Roth-C model, the ABMS should record:

- Area of each crop (ha)
- Productivity of each crop (kg/ha)
- The amount of crop residues (kg/ha)\(^ {12} \)
- Existing crop residue management practices and their frequency
- Future crop residue management practices that will be implemented with the project

If the project activity includes improving the management of manure, then for use with the Roth-C model, the ABMS should record:

- Area of grazing (ha)
- The number of livestock per animal type
- The amount of manure produced (kg/ha or kg/an)\(^ {13} \)
- Existing manure management practices and their frequency
- Future manure management practices that will be implemented with the project

If the project activity includes improved tillage practices, then for use with the Roth-C model, the ABMS should record:

- Area under tillage (ha)
- Type and depth of tillage
- Existing tilling practices and their frequency
- Future tilling practices that will be implemented with the project

\(^{12}\) Amount of crop residues need not be measured directly. It can also be estimated from the crop production using equations listed in Table 11.2 in Volume 4 of the 2006 IPCC Guidelines.

\(^{13}\) Amount of manure need not be measured directly. It can also be estimated from the number and type of animal using values from Table 10A-4 in Chapter 10 of the 2006 IPCC Guidelines.
If the project activity includes agroforestry, then for use with the Roth-C model, the ABMS should record:

- Area of agroforestry (ha)
- Number and species of trees used
- Diameter at breast height (DBH) of trees
- Future numbers of trees that will be implemented with the project

It is recommended that the project proponent stratifies the project area by crop system, tillage system, use of crop residues, application of manure and clay content of soils and relevant climatic variables as a minimum.

The applicability of the selected model and parameters recorded for the various activities, and soil and climate types are dependent on the actual project. Since these are project specific and not methodology specific, they should be discussed in detail in the project description.

Other model input parameters that may be required by the selected model, such as climatic data, clay content and texture of soils can be acquired from global or national data sets and do not need to be measured by the project proponent.

### III.1.6 Data to be collected and archived for leakage

The only source of leakage possible as a result of the project is the leakage from a switch to non-renewable biomass use attributable to the project. If the project plan includes the diversion of biomass used for cooking and heating to the fields (for example, manure or agricultural residuals) then the project proponent should estimate the possible leakage.

The project proponent should record the amount of biomass used for cooking and heating purposes that is diverted to the agricultural system. It is conservatively assumed that this is replaced by non-renewable biomass or locally used fossil fuels.

The ABMS survey is expected to provide information to assess whether or not non-renewable biomass from outside the project or fossil fuels are used for the purpose of cooking or heating by the surveyed project households to replace the biomass diverted to agricultural fields. If the ABMS survey data shows that 10% or fewer project households use non-renewable biomass from outside the project or fossil fuels to replace the biomass diverted to agricultural fields, then the leakage is considered insignificant and ignored.

In situations where ABMS survey data shows that more than 10% of the project households use non-renewable biomass from outside the project or fossil fuels to replace the biomass diverted to agricultural fields, then the leakage is considered significant and shall be estimated based on the household energy use information collected through the ABMS Survey to calculate the leakage.

\[
LHE_i = LNRB_i + LFF_i
\]

Where:

- \(LHE_i\)  
  The leakage from a switch to non-renewable biomass or fossil fuel in place of the biomass used for cooking/heating diverted to agricultural system in year \(t\), \(t\) CO₂e

- \(LNRB_i\)  
  Leakage from a switch to non-renewable biomass use in year \(t\), \(t\) CO₂e

### IV.2.7 Conservative approach

Since emissions reduced are calculated as the baseline emissions minus project emissions, an approach that:

1) ignores emissions in the baseline; and/or
2) ignores emission removals (sequestration) in the project

is conservative. Ignoring either of these two items will mean that emission reductions are underestimated.

The methodology uses a conservative approach because applicability conditions limit its use to:

a) Land is either cropland or grassland at the start of the project
b) The project does not occur on wetlands
c) The land is degraded and will continue to be degraded or continue to degrade
d) The area of land under cultivation is constant or increasing in absence of the project
e) Forest land, as defined by the national CDM forest definition, in the area is constant or decreasing over time

With these assumptions the methodology conservatively ignores emissions from SOC in the baseline.

The methodology uses a conservative approach because it assumes that leakage caused by the displacement of biomass used for cooking and heating purposes to the fields as the result of the project, causes an increase in the use of non-renewable biomass or fossil fuels.

### IV.2.8 Uncertainty analysis

The project proponent shall use the CDM EB approved General Guidelines for Sampling and Surveys for Small-Scale CDM Project Activities with a view to reducing uncertainty of model input
parameters. The generation of model parameters follows the standard procedures on surveys and quality assurance in the collection and organization of data.

The project proponent will estimate the uncertainty of the agricultural input parameters to the soil organic model using the ABMS as required under Section 4.1 of VCS standard v3.1.

If the project area is stratified, the sampling effort should represent the relevant strata in the sample frame. Where there is no specific survey guidance from national institutions, the project proponent shall use a precision of 15% at the 95% confidence level as the criteria for reliability of sampling efforts. This reliability specification shall be applied to determine the sampling requirements for assessing parameter values. The sampling intensity could be increased to ensure that the model parameters estimated from the ABMS lead to the achievement of a desired precision of 15% at the 95% confidence level for the estimate of greenhouse gas emission reductions from the project. The project proponent should calculate the soil model response using the model input parameters with the upper and lower confidence levels. The range of model responses demonstrates the uncertainty of the soil modelling.

**Step 1: Calculate the values for all input parameters at the upper and lower confidence limit.**

Calculate the mean, $X_p$ and standard deviation, $\hat{\sigma}_p$, for all parameters measured in ABMS, and then the standard error in the mean is given by:

$$SE_p = \frac{\hat{\sigma}_p}{\sqrt{n_p}}$$

Where:

$SE_p$ Standard error in the mean of parameter, $p$ in year $t$

$\hat{\sigma}_p$ The standard deviation of the parameter $p$ in year $t$

$n_p$ Number of samples used to calculate the mean and standard deviation of parameter $p$

Assuming that values of the parameter are normally distributed about the mean, the minimum and maximum values for the parameters are given by:

$$P_{\text{min}} = \bar{X}_p - 1.96 \times SE_p$$

$$P_{\text{max}} = \bar{X}_p + 1.96 \times SE_p$$

Where:

$P_{\text{min}}$ The minimum value of the parameter at the 95% confidence interval

$P_{\text{max}}$ The maximum value of the parameter at the 95% confidence interval

$SE_p$ Standard error in the mean of parameter, $p$ in year $t$

1.96 The value of the cumulative normal distribution at 95% confidence interval
Step 2: Calculate the project removals due to changes in soil organic carbon with the minimum and maximum values of the input parameters

The project removals due to changes in soil organic carbon using the minimum and maximum values of the parameters is given by

$$PRS_{\text{min},t} = \text{Model}(P_{\text{min}}, \text{Temperature}_{\text{max}}, \text{Precipitatio}_{\text{max}}, \text{ClayContent}_{\text{min}})$$

$$PRS_{\text{max},t} = \text{Model}(P_{\text{max}}, \text{Temperature}_{\text{min}}, \text{Precipitatio}_{\text{min}}, \text{ClayContent}_{\text{max}})$$

Where:

- $PRS_{\text{min},t}$: The minimum value of project removals due to changes in soil organic carbon at the 95% confidence interval
- $PRS_{\text{max},t}$: The maximum value of project removals due to changes in soil organic carbon at the 95% confidence interval

Step 3: Calculate the uncertainty in the model output

The uncertainty in the output model is given by:

$$UNC_t = \left[\frac{PRS_{\text{max},t} - PRS_{\text{min},t}}{2 * PRS_t}\right]$$

Step 4: Adjust the estimate of soil sequestration based on the uncertainty in the model output

If the uncertainty of soil models is less than or equal to 15% of the mean value then the project proponent may use the estimated value without any deduction for conservativeness or increase in sampling.

If the uncertainty of soil models is greater than 15% but less than or equal to 30% of the mean value, then the project proponent may use the estimated value subject to a deduction calculated as

$$PRS_{\text{Deduction},t} = PRS_t * (UNC_t - 15\%)$$

And the following term will be used in equation 7 in place of $PRS_t$

$$PRS_{\text{Adj},t} = PRS_t - PRS_{\text{Deduction},t}$$

Where:

- $PRS_t$: Estimate of project removals due to changes in soil organic carbon in year $t$, t CO$_2$e.
- $PRS_{\text{Unc}}$: Estimate of uncertainty in the mean of changes in soil organic carbon in year $t$, t CO$_2$e.
- $PRS_{\text{Deduction},t}$: A calculated deduction to the estimate of the change in soil organic removals year $t$, t CO$_2$e.
- $PRS_{\text{Adj},t}$: An adjusted estimate of project removals due to changes in soil organic carbon in year $t$, t CO$_2$e.

In this way, when the uncertainty is 15% or less than 15% there is no deduction and when the uncertainty is between 15 and 30% a deduction as calculated in Step 4 above will apply.
If the uncertainty of soil models is greater than 30% of the mean value then the project proponent should increase the sample size of the input parameters until the soil model uncertainty is better than ± 30%.

IV.2.9 Other information

Every five years the means of parameters will be tested for significant difference using t-tests. If the means are significantly different then the soil model shall be updated based on the new data and relevant data such as studies conducted in the region. It is not incumbent that the project proponent shall undertake such studies as part of the project activity but shall make use of data generated elsewhere as part of ongoing research/other efforts in the region for updating the model. Such data can be used to refine the model over time and decrease uncertainty.

Section V: Lists of variables, acronyms and references

V.1 Variables used in equations

Equation 1

\[ BS_{\text{equil},t} \] Baseline SOC in equilibrium year \( t \), tC

\[ BA_{C,m,t} \] Baseline areas in cropland with management practice, \( m_C \), year \( t \), ha

\[ SOC_{C,m,t} \] Soil organic carbon density at equilibrium for cropland with management practice, \( m_C \), tC/ha

\( m_C \) An index for cropland management types, unit less

\[ BA_{G,m,t} \] Baseline areas in grassland with management practice, \( m_G \), year \( t \), ha

\[ SOC_{G,m,t} \] Soil organic carbon density at equilibrium for grassland with management practice, \( m_G \), tC/ha

\( m_G \) An index for grassland management types, unit less

Equation 2

\[ BRS_t \] Baseline removals due to changes in soil organic carbon in year \( t \), t CO\(_2\)e.

Equation 3

\[ BE_t \] Baseline emissions in year \( t \), t CO\(_2\)e

\[ BEF_t \] Baseline emissions due to nitrogen fertilizer use in year \( t \), t CO\(_2\)e.

\[ BEFF_t \] Baseline emissions due to use of fossil fuels in agricultural management in year \( t \), t CO\(_2\)e.

\[ BEN_t \] Baseline emissions due to the use of N-fixing species in year \( t \), t CO\(_2\)e.

\[ BEBB_t \] Baseline emissions due to biomass burning in year \( t \), t CO\(_2\)e.

\[ BRWP_t \] Baseline removals due to changes in woody perennials in year \( t \), t CO\(_2\)e.
Equation 4

\[ PS_{\text{equil},t} \]  Project SOC in equilibrium year \( t \), tC

\[ PA_{C,mC,t} \]  Project areas in cropland with management practice, \( m_C \), year \( t \), ha

\[ SOC_{C,mC,t} \]  Soil organic carbon density at equilibrium for cropland with management practice, \( m_C \), at year \( t \), tC/ha

\( m_C \)  An index for cropland management types, unit less

\[ PA_{G,mG,t} \]  Project areas in grassland with management practice, \( m_G \), year \( t \), ha

\[ SOC_{G,mG,t} \]  Soil organic carbon density at equilibrium for grassland with management practice, \( m_G \), at year \( t \), tC/ha

\( m_G \)  An index for grassland management types, unit less

Equation 5

\[ PS_t \]  Project estimate of the project SOC in year \( t \), tC

\[ PS_{\text{equil},t} \]  Project estimate of the project SOC in equilibrium year \( t \), tC

\( D \)  The transition period required for SOC to be at equilibrium after a change in land use or management practice, year

\( \Delta t \)  Time increment = 1 year

Equation 6

\[ PRS_t \]  Estimate of project removals due to changes in soil organic carbon in year \( t \), t CO2e.

\[ PS_t \]  Estimate of the project SOC in year \( t \), tC

Equation 7

\[ PE_t \]  Estimate of actual net GHG emissions and removals by sinks in year \( t \), t CO2e

\[ PEF_t \]  Estimate of project emissions due to nitrogen fertilizer use in year \( t \), t CO2e.

\[ PEFF_t \]  Estimate of project emissions due to burning of fossil fuels for agricultural management in year \( t \), t CO2e.

\[ PEN_t \]  Estimate of project emissions due to the use of N-fixing species in year \( t \), t CO2e.

\[ PEBB_t \]  Estimate of project emissions due to biomass burning in year \( t \), t CO2e.

\[ PRWP_t \]  Estimate of project due to changes in biomass of woody perennials in year \( t \), t CO2e.

\[ PRS_t \]  Estimate of project removals due to changes in soil organic carbon in year \( t \), t CO2e.
Equation 8
\[ \Delta R_t \] Estimate of net anthropogenic GHG emissions and removals in year \( t \), t CO\(_2\)e
\[ PE_t \] Estimate of actual net GHG emissions and removals in year \( t \), t CO\(_2\)e
\[ BE_t \] Baseline emissions and removals in year \( t \), t CO\(_2\)e
\[ LHE_t \] The leakage from a switch to non-renewable biomass or fossil fuel in place of the biomass used for cooking/heating diverted to agricultural system in year \( t \), t CO\(_2\)e

Equation 9
\[ LHE_t \] The leakage from a switch to non-renewable biomass or fossil fuel in place of the biomass used for cooking/heating diverted to agricultural system in year \( t \), t CO\(_2\)e
\[ LNRB_t \] Leakage from a switch to non-renewable biomass use in year \( t \), t CO\(_2\)e
\[ LFF_t \] Leakage from switch to fossil fuel in year \( t \), t CO\(_2\)e

Equation 10
\[ LNRB_t \] Leakage from a switch to non-renewable biomass use in year \( t \), t CO\(_2\)e
\[ B_{\text{biomass},t} \] Quantity of biomass from outside the project used in place of the biomass used for cooking/heating diverted to agricultural system in year \( t \), tonnes
\[ f\text{NRB} \] Fraction of non-renewable biomass from outside the project in year \( t \)
\[ NCV_{\text{biomass}} \] Net calorific value of the non-renewable biomass from outside the project
\[ EF_{\text{fossil fuel}} \] Emission factor of fossil fuel as substitute for non-renewable biomass

Equation 11
\[ B_{\text{fossil fuel},t} \] Quantity of fossil fuel used in place of the biomass used for cooking/heating diverted to agricultural system in year \( t \), tonnes
\[ NCV_{\text{fossil fuel}} \] Net calorific value of the fossil that is substituted
\[ EF_{\text{fossil fuel}} \] Emission factor of fossil fuel as a substitution for non-renewable biomass

Equation 12
\[ SE_p \] Standard error in the mean of parameter, \( p \) in year \( t \)
\[ \hat{\sigma}_p \] The standard deviation of the parameter \( p \) in year \( t \)
\[ n_p \] Number of samples used to calculate the mean and standard deviation of parameter \( p \)
Standard error in the mean of parameter, $p$ in year $t$

**Equation 13**

- $P_{\text{min}}$ The minimum value of the parameter at the 95% confidence interval
- $P_{\text{max}}$ The maximum value of the parameter at the 95% confidence interval
- $SE_p$ Standard error in the mean of parameter, $p$ in year $t$
- 1.96 The value of the cumulative normal distribution at 95% confidence interval

**Equation 14, 15**

- $PRS_{\text{min},t}$ The minimum value of project removals due to changes in soil organic carbon at the 95% confidence interval
- $PRS_{\text{max},t}$ The maximum value of project removals due to changes in soil organic carbon at the 95% confidence interval

**Equation 16, 17**

- $PRS_t$ Estimate of project removals due to changes in soil organic carbon in year $t$, t CO$_2$e.
- $PRS_{\text{Unc}}$ Estimate of uncertainty in the mean of changes in soil organic carbon in year $t$, t CO$_2$e.
- $PRS_{\text{Deduction}}$ A calculated deduction to the estimate of the change in soil organic removals year $t$, t CO$_2$e.
- $PRS_{\text{Adj},t}$ An adjusted estimate of project removals due to changes in soil organic carbon in year $t$, t CO$_2$e.

- SOC soil organic carbon
Section VI: Tools

VI.1 Estimation of direct nitrous oxide emission from N-fixing species and crop residues

This tool can be used for both ex ante and ex post estimation of the nitrous oxide emissions from the use of nitrogen fixing species and crop residues within the boundary of a VCS project. For ex post estimation purposes, activity data (quantities of crop residues) are monitored or estimated.

It is important to note that for the project emissions, it is only the new area under N-fixing crop that is input to the formulae.

As the project proponent may use various N-fixing species, it is important to identify and record the species type and estimate the amount of inputs from each species. The direct nitrous oxide emissions from the use of nitrogen fixing species and crop residues can be estimated using equations as follows:

\[
N_2O_{direct-N,t} = F_{CR,t} \cdot EF_1 \cdot MW_{N_2O} \cdot GWP_{N_2O} \cdot 10^{-3}
\]

\[
F_{CR,t} = \sum_{i} \left( \text{Area}_{i,t} - \text{Area}_{burnt,i,t} \cdot C_f \right) \cdot \text{Frac}_{\text{Renew}} \cdot \left[ R_{\text{AG,i,t}} \cdot N_{\text{AG,i,t}} \cdot (1 - \text{Frac}_{\text{Renew}}) \right] + R_{\text{BG,i,t}} \cdot N_{\text{BG,i,t}}
\]

Where:

<table>
<thead>
<tr>
<th>(N_2O_{direct-N,t})</th>
<th>Direct N(_2)O emission as a result of nitrogen application within the project boundary, t-CO(_2)-e in year t</th>
</tr>
</thead>
<tbody>
<tr>
<td>(F_{CR,t})</td>
<td>Amount of N in crop residues (above and below ground), including N-fixing crops returned to soils annually, kg N yr(^{-1}) in year t</td>
</tr>
<tr>
<td>(EF_1)</td>
<td>Emission Factor for emissions from N inputs, tonne-N(_2)O-N (tonne-N input)(^{-1}) As noted in IPCC 2006 Guidelines (table 11.1), the default emission factor ((EF_1)) is 1% of applied N, and this value should be used when country-specific factors are unavailable. The project proponent may use emission factors from the peer reviewed scientific literature that are specific for the project area.</td>
</tr>
<tr>
<td>(MW_{N_2O})</td>
<td>Ratio of molecular weights of N(_2)O and N (44/28), tonne-N(_2)O (t-N)(^{-1})</td>
</tr>
<tr>
<td>(GWP_{N_2O})</td>
<td>Global Warming Potential for N(_2)O, kg-CO(_2)-e (kg-N(_2)O)(^{-1}) (IPCC default = 310, valid for the first commitment period).</td>
</tr>
<tr>
<td>(Crop_{i,t})</td>
<td>Harvested annual dry matter yield for crop i in year t, kg d.m. ha(^{-1}) For N-fixing trees use the above ground biomass.</td>
</tr>
<tr>
<td>(Area_{i,t})</td>
<td>total annual area harvested of N-fixing crop i or trees i in year t, ha yr(^{-1})</td>
</tr>
<tr>
<td>(Area_{burnt,i,t})</td>
<td>annual area of N-fixing crop i or trees burnt in year t, ha yr(^{-1})</td>
</tr>
<tr>
<td>(C_f)</td>
<td>combustion factor (dimensionless) (see 2006 IPCC Guidelines, Table 2.6)</td>
</tr>
<tr>
<td>(\text{Frac}_{\text{Renew}})</td>
<td>fraction of total area under crop that is renewed annually. For countries where pastures are renewed on average every X years, (\text{Frac}<em>{\text{Renew}} = 1/X). For annual crops (\text{Frac}</em>{\text{Renew}} = 1). For N-fixing trees assume that they shed their leaves at harvest.</td>
</tr>
</tbody>
</table>
leaves every year are similar to annual crops

\[ R_{AG,i,t} \]

ratio of above-ground residues dry matter (\( AG_{DM,i,t} \)) to harvested yield for crop \( i \) in year \( t \) (\( Crop_{i,t} \)), kg d.m. (kg d.m.)\(^{-1}\)

(see 2006 IPCC Guidelines, Table 11.2)

For NB-fixing trees use the ratio of leaf biomass to above ground biomass.

For deciduous trees 0.02 is a reasonable value

\[ N_{AG,i,t} \]

N content of above-ground residues for crop \( i \), kg N (kg d.m.)\(^{-1}\)

(see 2006 IPCC Guidelines, Table 11.2)

For N-fixing trees assume 0.027 (default value for N-fixing forages) This value should be used when country-specific factors are unavailable.

\[ Frac_{\text{Removed}} \]

Fraction of above-ground residues of crop \( i \) removed annually for purposes such as feed, bedding and construction, kg N (kg crop-N)\(^{-1}\). Survey of experts in country is required to obtain data.

If data for \( Frac_{\text{Removed}} \) are not available, assume no removal.

\[ R_{BG,i,t} \]

Ratio of below-ground residues to harvested yield for crop \( i \), kg d.m. (kg d.m.)\(^{-1}\).

(see 2006 IPCC Guidelines, Table 11.2)

For N-fixing trees assume 0.01 (assumes that fine roots are 7% of total root biomass, that total root biomass is 25% of above ground biomass and there is a 50% fine root turnover). This value should be used when country-specific factors are unavailable.

\[ N_{BG,i,t} \]

N content of below-ground residues for crop \( i \), kg N (kg d.m.)\(^{-1}\).

(see 2006 IPCC Guidelines, Table 11.2)

For N-fixing trees assume 0.022 (default value for N-fixing forages) This value should be used when country-specific factors are unavailable.

**VI.2 Estimation of emissions from the use of fossil fuels in agricultural management**

The following tool is derived from the A/R Methodological Tool *Estimation of GHG emissions related to fossil fuel combustion in A/R CDM project activities*. The \( \text{CO}_2 \) emissions are calculated using the following equations:

\[ EFF_t = \sum_{j=1}^{J} ET_{j,t} \]

Where:

\( EFF_t \) Emissions due to the use of fossil fuels in agricultural management, t \( \text{CO}_2\text{e} \)

Note: in the methodology there is a prefix B or P depending on whether they are baseline or project emissions

\( ET_{j,t} \) Emission from fossil fuel combustion in vehicle/equipment type \( j \) during year \( t \), t \( \text{CO}_2\text{e}/yr \)

\( j \) Type of vehicle/equipment

\( J \) Total number of types of vehicle/equipment used in the project activity
It is assumed that the amount of fuel combusted is available. The method may be used in estimating vehicle/equipment emission, when the vehicle/equipment is captive (i.e. controlled by the project proponent) and the entire fuel consumption can be monitored. If this is not available, the amount of fuel combusted can be estimated using fuel efficiency (for example l/100 km, l/t-km, l/hour) of the vehicle and the appropriate unit of use for the selected fuel efficiency (for example km driven if efficiency is given in l/100 km). The equation is as follows.

\[ ET_{j,t} = FC_{j,t} \cdot EF_{CO2,j} \]

Where:

- \( ET_{j,t} \): Emission from fossil fuel combustion in vehicle/equipment type \( j \) during year \( t \), t CO\(_2\)e/yr
- \( FC_{j,t} \): Consumption of fossil fuel in vehicle/equipment type \( j \) during year \( t \), litres/yr
- \( EF_{CO2,j} \): Emission factor for the type of fossil fuel combusted in vehicle or equipment, \( j \)

For gasoline \( EF_{CO2} = 0.002810 \) t per litre. For diesel \( EF_{CO2} = 0.002886 \) t per litre\(^ {14} \)

\( j \) Type of vehicle/equipment
\( J \) Total number of types of vehicle/equipment used in the project activity

### VI.3 Estimation of non-CO\(_2\) emissions from the burning of crop residues

The CO\(_2\) emissions from the burning of crop residues and grasslands are not included in the methodology as per IPCC convention. The non-CO\(_2\) emissions burning this biomass, \( EBB_t \), are calculated using the following equations:

\[
EBB_t = \left[ MB_{C,t} \cdot C_F \cdot \left( 2.7 \cdot GWP_{CH4} + 0.07 \cdot GWP_{N2O} \right) + MB_{G,t} \cdot C_F \cdot \left( 2.3 \cdot GWP_{CH4} + 0.21 \cdot GWP_{N2O} \right) \right] \cdot 10^{-3}
\]

Where:

- \( EBB_t \): Emissions due to biomass burning in year \( t \), t CO\(_2\)e
- \( MB_{C,t} \): Mass of crop residues burnt in year \( t \), tonnes
- \( 2.7, 0.07 \): Emissions factors for the burning of cropland, g CH\(_4\) / kg and g N\(_2\)O / kg, respectively
  - From Table 2.5, 2006 IPCC Guidelines for National Greenhouse Gas Inventories
- \( MB_{G,t} \): Mass of grasslands residues burnt in year \( t \), tonnes
- \( 2.3, 0.21 \): Emissions factors for the burning of grassland, g CH\(_4\) / kg and g N\(_2\)O / kg, respectively
  - From Table 2.5, 2006 IPCC Guidelines for National Greenhouse Gas Inventories
- \( GWP_{CH4} \): Global warming potential of CH\(_4\) (IPCC default: 21 for the first commitment period of the Kyoto Protocol); t CO\(_2\)e / t CH\(_4\)
- \( C_F \): Combustion factors that depend on vegetation type (see Table 4), unit less

\(^ {14} \): These values calculated from IPCC 2006 Table 3.3.1 assuming 2-stroke gasoline engine for gasoline combustion and default values for energy content of 47.1 GJ/t and 45.66 GJ/t for gasoline and diesel respectively (IEA. 2004. Energy Statistics Manual. http://www.iea.org/stats/docs/statistics_manual.pdf)
